The artifact I selected is an Android inventory management application that I originally created in a previous mobile development course. The application allows users to create an account, log in, and manage inventory stored in a local SQLite database. Users can add and remove items, change quantities, and receive feedback when an item reaches zero.

I selected this artifact because it does a good job highlighting different areas of software development. The original application was functional, but there were glaring flaws and too much of the logic was contained in MainActivity. I improved the application with this enhancement by creating an InventoryItem model, separating the login and inventory functionality into different activities, upgrading input validation, and improving navigation and the user interface. I also began restructuring the inventory display using a RecyclerView in hopes of having a more maintainable app (GeeksforGeeks, 2025).

I believe this enhancement met the outcomes I originally selected. The process required me to evaluate an existing application and make decisions about how its design could be improved. I also used Android development techniques and object-oriented design principles to make the application more maintainable. I do not currently have any major changes to my planned course outcomes.

The biggest thing I learned from this enhancement was just how much of the code could be changed without actually showing any visual changes. Separating responsibilities into different classes made it easier to understand what each part of the application was responsible for. One challenge was making major structural changes without breaking code that already worked.
